Bias-Variance trade-off for ridge regression

BIAS-VARIANCE DECOMPOSITION FOR RIDGE I

For a linear model $\mathbf{y} = \mathbf{X}\boldsymbol{\theta} + \boldsymbol{\varepsilon}$ with fixed design $\mathbf{X} \in \mathbb{R}^{n \times p}$ and $\boldsymbol{\varepsilon} \sim (\mathbf{0}, \sigma^2 \mathbf{I}_n)$, bias of ridge estimator $\hat{\theta}_{\text{ridge}}$ is given by

$$\begin{aligned} \mathsf{Bias}(\hat{\theta}_{\mathsf{ridge}}) &:= \mathbb{E}[\hat{\theta}_{\mathsf{ridge}} - \boldsymbol{\theta}] = \mathbb{E}[(\boldsymbol{X}^{\top}\boldsymbol{X} + \lambda \boldsymbol{I}_{p})^{-1}\boldsymbol{X}^{\top}\boldsymbol{y}] - \boldsymbol{\theta} \\ &= \mathbb{E}[(\boldsymbol{X}^{\top}\boldsymbol{X} + \lambda \boldsymbol{I}_{p})^{-1}\boldsymbol{X}^{\top}(\boldsymbol{X}\boldsymbol{\theta} + \boldsymbol{\varepsilon})] - \boldsymbol{\theta} \\ &= (\boldsymbol{X}^{\top}\boldsymbol{X} + \lambda \boldsymbol{I}_{p})^{-1}\boldsymbol{X}^{\top}\boldsymbol{X}\boldsymbol{\theta} + (\boldsymbol{X}^{\top}\boldsymbol{X} + \lambda \boldsymbol{I}_{p})^{-1}\boldsymbol{X}^{\top}\underbrace{\mathbb{E}[\boldsymbol{\varepsilon}]}_{=0} - \boldsymbol{\theta} \\ &= (\boldsymbol{X}^{\top}\boldsymbol{X} + \lambda \boldsymbol{I}_{p})^{-1}\boldsymbol{X}^{\top}\boldsymbol{X}\boldsymbol{\theta} - \boldsymbol{\theta} \\ &= \left[(\boldsymbol{X}^{\top}\boldsymbol{X} + \lambda \boldsymbol{I}_{p})^{-1} - (\boldsymbol{X}^{\top}\boldsymbol{X})^{-1}\right]\boldsymbol{X}^{\top}\boldsymbol{X}\boldsymbol{\theta} \end{aligned}$$

- Last expression shows bias of ridge estimator only vanishes for $\lambda = 0$, which is simply (unbiased) OLS solution
- It follows $\| {\sf Bias}(\hat{ heta}_{\sf ridge}) \|_2^2 > 0$ for all $\lambda > 0$

BIAS-VARIANCE DECOMPOSITION FOR RIDGE II

For the variance of $\hat{\theta}_{\text{ridge}}$, we have

$$\begin{aligned} \operatorname{Var}(\hat{\theta}_{\mathsf{ridge}}) &= \operatorname{Var}\left((\boldsymbol{X}^{\top}\boldsymbol{X} + \lambda \boldsymbol{I}_{p})^{-1}\boldsymbol{X}^{\top}\boldsymbol{y}\right) & | \operatorname{apply} \operatorname{Var}_{u}(\boldsymbol{A}\boldsymbol{u}) = \boldsymbol{A}\operatorname{Var}(\boldsymbol{u})\boldsymbol{A}^{\top} \\ &= (\boldsymbol{X}^{\top}\boldsymbol{X} + \lambda \boldsymbol{I}_{p})^{-1}\boldsymbol{X}^{\top}\operatorname{Var}(\boldsymbol{y})\left((\boldsymbol{X}^{\top}\boldsymbol{X} + \lambda \boldsymbol{I}_{p})^{-1}\boldsymbol{X}^{\top}\right)^{\top} \\ &= (\boldsymbol{X}^{\top}\boldsymbol{X} + \lambda \boldsymbol{I}_{p})^{-1}\boldsymbol{X}^{\top}\operatorname{Var}(\boldsymbol{\varepsilon})\boldsymbol{X}(\boldsymbol{X}^{\top}\boldsymbol{X} + \lambda \boldsymbol{I}_{p})^{-1} \\ &= (\boldsymbol{X}^{\top}\boldsymbol{X} + \lambda \boldsymbol{I}_{p})^{-1}\boldsymbol{X}^{\top}\boldsymbol{\sigma}^{2}\boldsymbol{I}_{n}\boldsymbol{X}(\boldsymbol{X}^{\top}\boldsymbol{X} + \lambda \boldsymbol{I}_{p})^{-1} \\ &= \boldsymbol{\sigma}^{2}(\boldsymbol{X}^{\top}\boldsymbol{X} + \lambda \boldsymbol{I}_{p})^{-1}\boldsymbol{X}^{\top}\boldsymbol{X}(\boldsymbol{X}^{\top}\boldsymbol{X} + \lambda \boldsymbol{I}_{p})^{-1} \end{aligned}$$

- $Var(\hat{\theta}_{ridge})$ is strictly smaller than $Var(\hat{\theta}_{OLS}) = \sigma^2(\mathbf{X}^{\top}\mathbf{X})^{-1}$ for any $\lambda > 0$, meaning matrix of their difference $Var(\hat{\theta}_{OLS}) Var(\hat{\theta}_{ridge})$ is positive definite (bit tedious derivation)
- ullet This further means trace $\left(\mathsf{Var}(\hat{ heta}_{\mathsf{OLS}}) \mathsf{Var}(\hat{ heta}_{\mathsf{ridge}}) \right) > 0 \, orall \lambda > 0$

BIAS-VARIANCE DECOMPOSITION FOR RIDGE III

Having obtained the bias and variance of the ridge estimator, we can decompose its mean squared error as follows:

$$\mathsf{MSE}(\hat{\theta}_{\mathsf{ridge}}) = \|\mathsf{Bias}(\hat{\theta}_{\mathsf{ridge}})\|_2^2 + \mathsf{trace}\big(\mathsf{Var}(\hat{\theta}_{\mathsf{ridge}})\big)$$

Comparing MSEs of $\hat{\theta}_{\text{ridge}}$ and $\hat{\theta}_{\text{OLS}}$ and using $\text{Bias}(\hat{\theta}_{\text{OLS}})=0$ we find

$$\mathsf{MSE}(\hat{\theta}_{\mathsf{OLS}}) - \mathsf{MSE}(\hat{\theta}_{\mathsf{ridge}}) = \underbrace{\mathsf{trace}\big(\mathsf{Var}(\hat{\theta}_{\mathsf{OLS}}) - \mathsf{Var}(\hat{\theta}_{\mathsf{ridge}})\big)}_{>0} - \underbrace{\|\mathsf{Bias}(\hat{\theta}_{\mathsf{ridge}})\|_2^2}_{>0}$$

Since both terms are positive, sign of their diff is *a priori* undetermined.
• Theobald 1974 and • Farebrother 1976 prove there always exists some $\lambda^* > 0$ so that

$$\mathsf{MSE}(\hat{ heta}_\mathsf{OLS}) - \mathsf{MSE}(\hat{ heta}_\mathsf{ridge}) > 0$$

Important theoretical result: While Gauss-Markov guarantuees $\hat{\theta}_{\text{OLS}}$ is best linear unbiased estimator (BLUE), there are biased estimators with lower MSE.

BIAS-VARIANCE IN PREDICTIONS FOR RIDGE I

In supervised learning, our goal is typically not to learn an unknown parameter θ , but to learn a function $f(\mathbf{x})$ that can predict y given \mathbf{x} .

The bias and variance of predictions $\hat{f} := \hat{f}(\mathbf{x}) = \hat{\theta}_{\mathsf{ridge}}^{\top} \mathbf{x}$ is obtained as:

$$\begin{aligned} \mathsf{Bias}(\hat{f}) &= \mathbb{E}[\hat{f} - f] = \mathbb{E}[\hat{\theta}_{\mathsf{ridge}}^{\top} \mathbf{x} - \boldsymbol{\theta}^{\top} \mathbf{x}] = \mathbb{E}[\hat{\theta}_{\mathsf{ridge}} - \boldsymbol{\theta}]^{\top} \mathbf{x} \\ &= \mathsf{Bias}(\hat{\theta}_{\mathsf{ridge}})^{\top} \mathbf{x} \\ \mathsf{Var}(\hat{f}) &= \mathsf{Var}(\hat{\theta}_{\mathsf{ridge}}^{\top} \mathbf{x}) = \mathbf{x}^{\top} \mathsf{Var}(\hat{\theta}_{\mathsf{ridge}}) \mathbf{x} \end{aligned}$$

The MSE of \hat{f} given a fresh sample (y, \mathbf{x}) can now be decomposed as

$$MSE(\hat{t}) = \mathbb{E}[(y - \hat{t}(\mathbf{x}))^2] = Bias^2(\hat{t}) + Var(\hat{t}) + \sigma^2$$

This decomposition is similar to the statistical inference setting before, however, the irreducible error σ^2 only appears for predictions as an artifact of the noise in the test sample.
